

Roman Coronagraph School Europe 2026

Debris disks

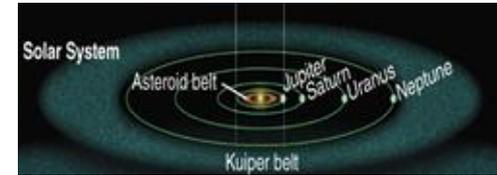

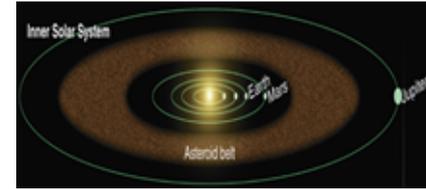

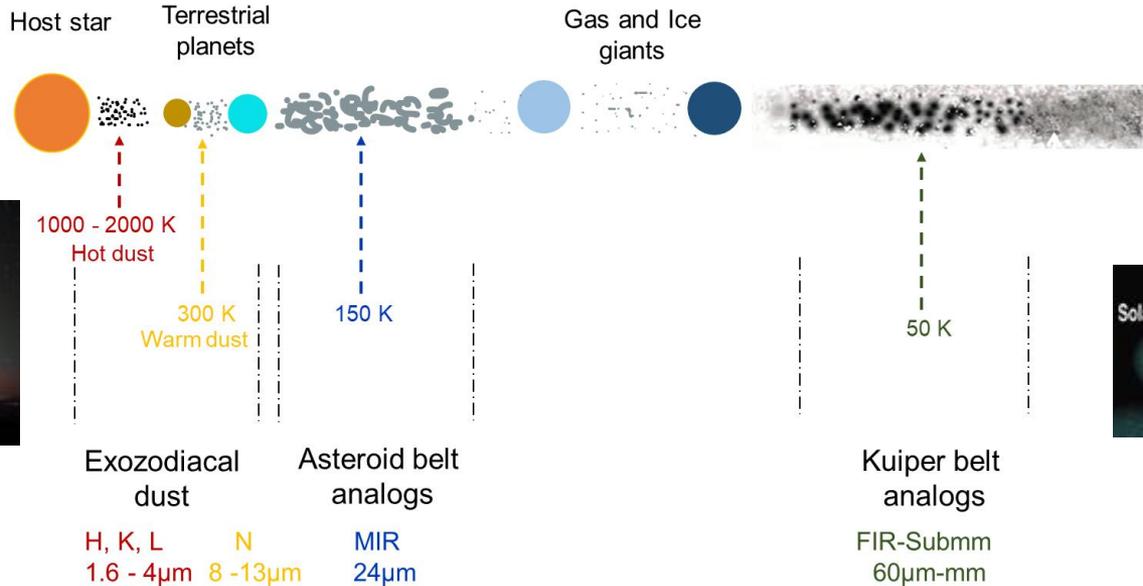

Isa Rebollido and Ramya Anche

Anatomy of a Debris disk system

Asteroid belts

Located near the water-icelines, these belts are made up of mostly rocky bodies, likely shepherded by gas giants that formed at the ice-line

Kuiper belts

These belts of Icy planetesimals

Adapted from Gaspar et al. 2019; Youdin & Rieke 2015)

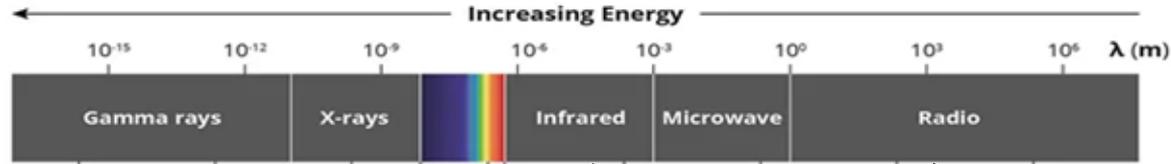

Dust in Debris disk

Dust in debris disk is seen in Scattered light and thermal emission

- Scattered light. This is where light from a star gets reflected off a dust grain. – Optical wavelengths
- Thermal emission. This is where a grain radiates heat as photons. – IR and Radio
- **‘Cold dust’**: dust at temperatures of order 30 K. Located in the outer regions of planetary systems, at 10s to 100s of au from stars.
- **‘Warm dust’**: temperatures of order 300 K. Distances of order 1 au, which is near the habitable zone.
- **‘Hot dust’**: temperatures of order 1000 K. Located very close to stars, at 0.1 au or less.

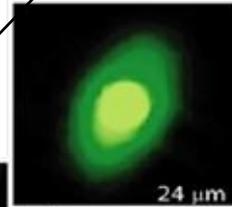

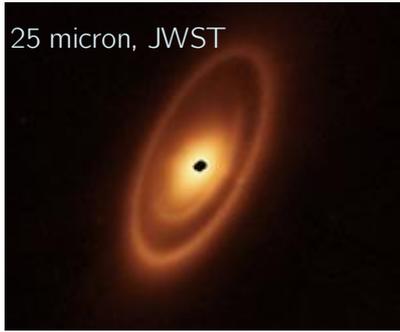

Observational Signatures of Debris Disks

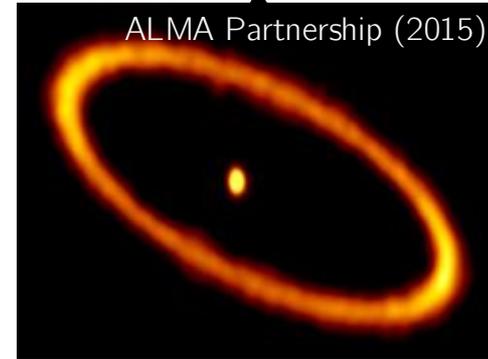

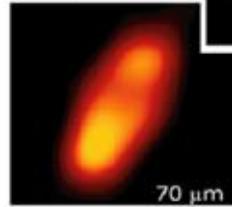

Gaspar et al. 2023

25 micron, JWST

Stapelfeldt et al. 2004

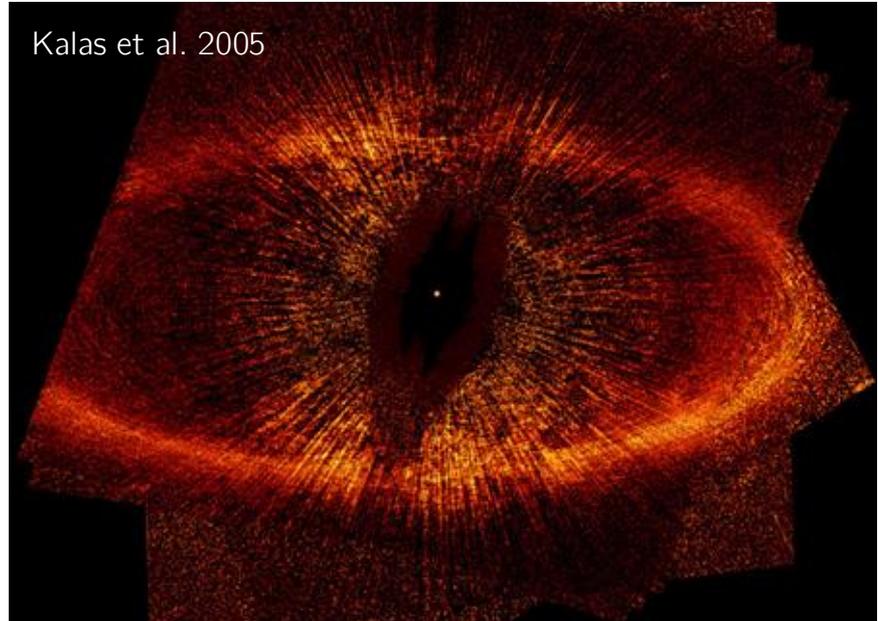

McGregor et al. 2017

IR is sensitive to thermal emission from the dust grains

Observational Signatures of Debris Disks

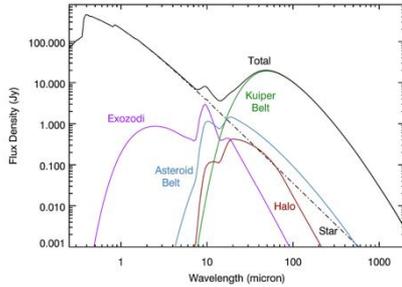

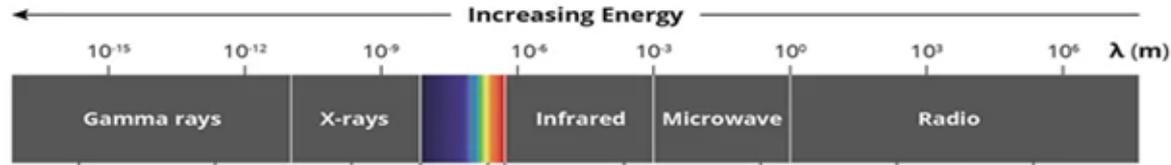

In the Optical and NIR, we image light scattered off of the smallest dust grains.

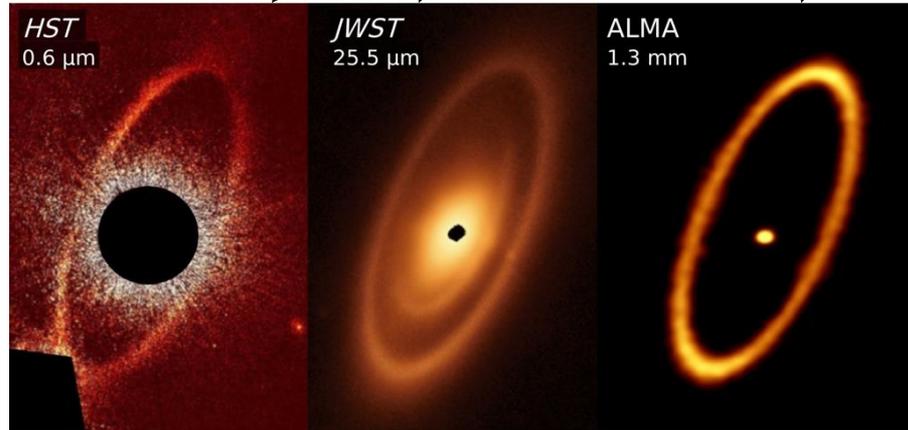

Observational Signatures of Debris Disks

In the Optical, light scattered from the smallest dust grains.

Infrared and Radio is sensitive to thermal emission from the large dust grains

Structural Diversity

Signs of planets

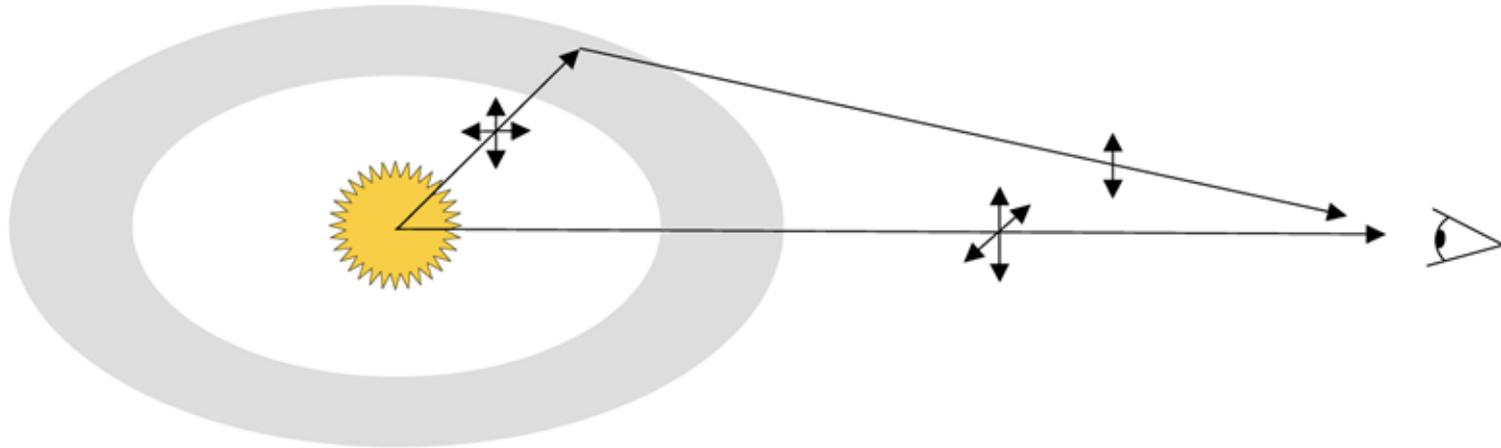

Debris disks are also polarized

Scattered light from debris disks is expected to be linearly polarized to some degree

- Asymmetries in their structure
- Scattering/absorption by the dust grains

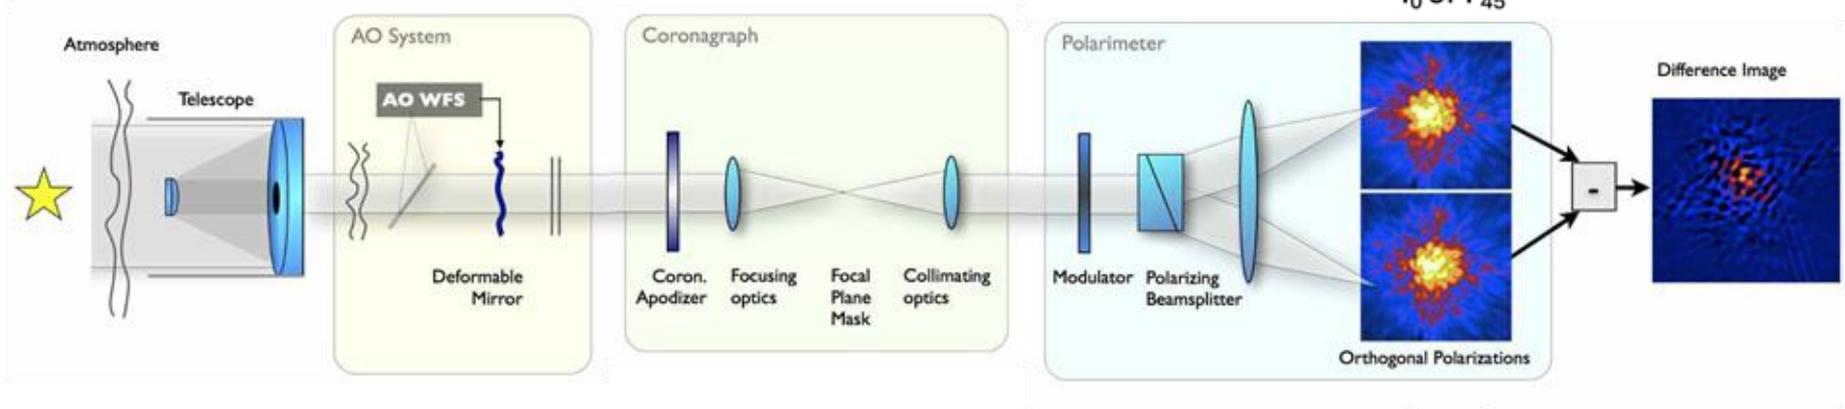

High-contrast polarimetry

Perrin, M. et al (2015)

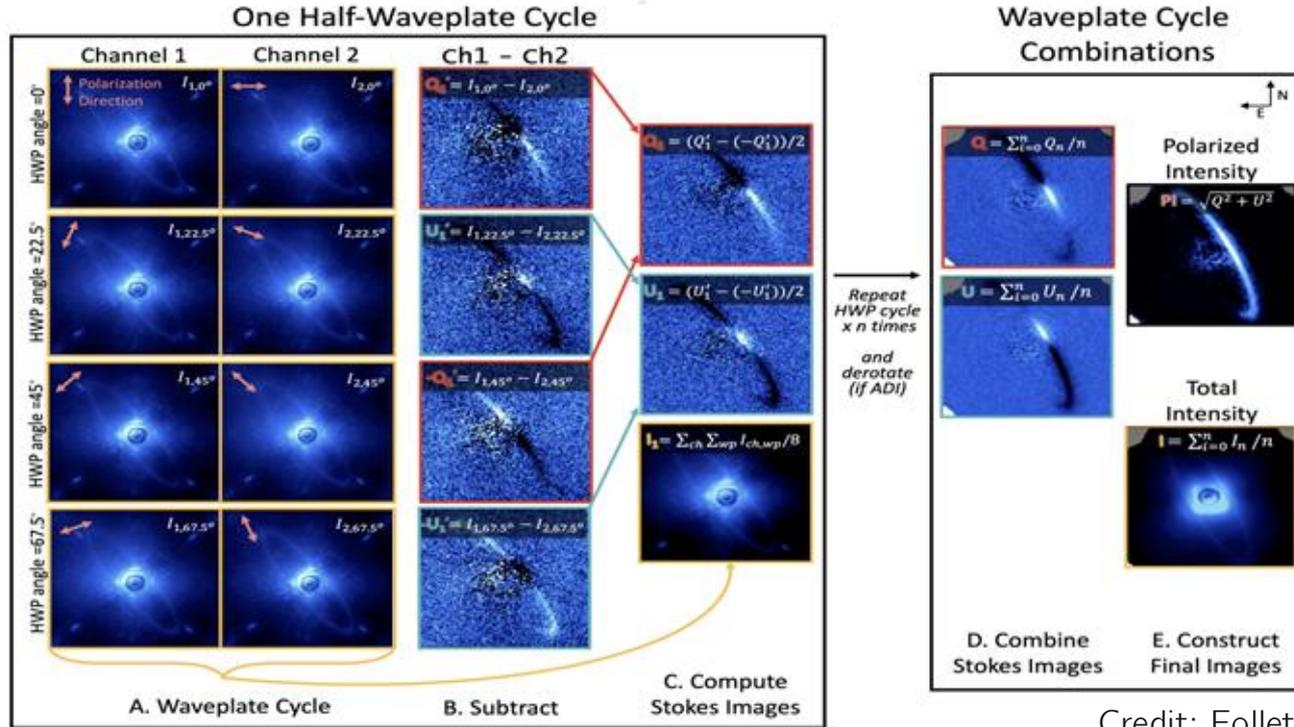

$$q = \frac{I(0) - I(90)}{I(0) + I(90)} \quad u = \frac{I(45) - I(135)}{I(45) + I(135)}$$

$$\text{Degree of Linear Polarization: } \sqrt{q^2 + u^2}$$

- eps_eri_0.6micron.fits

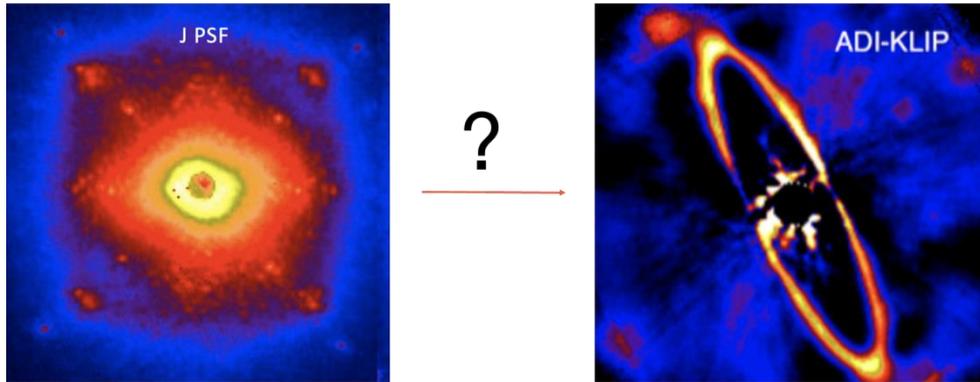

- What features can you understand from these multi wavelength observations?

Disk images require post-processing

The challenge = removing starlight to see the fainter disk

The (common) solution = PSF (point spread function) subtraction using a differential imaging technique:

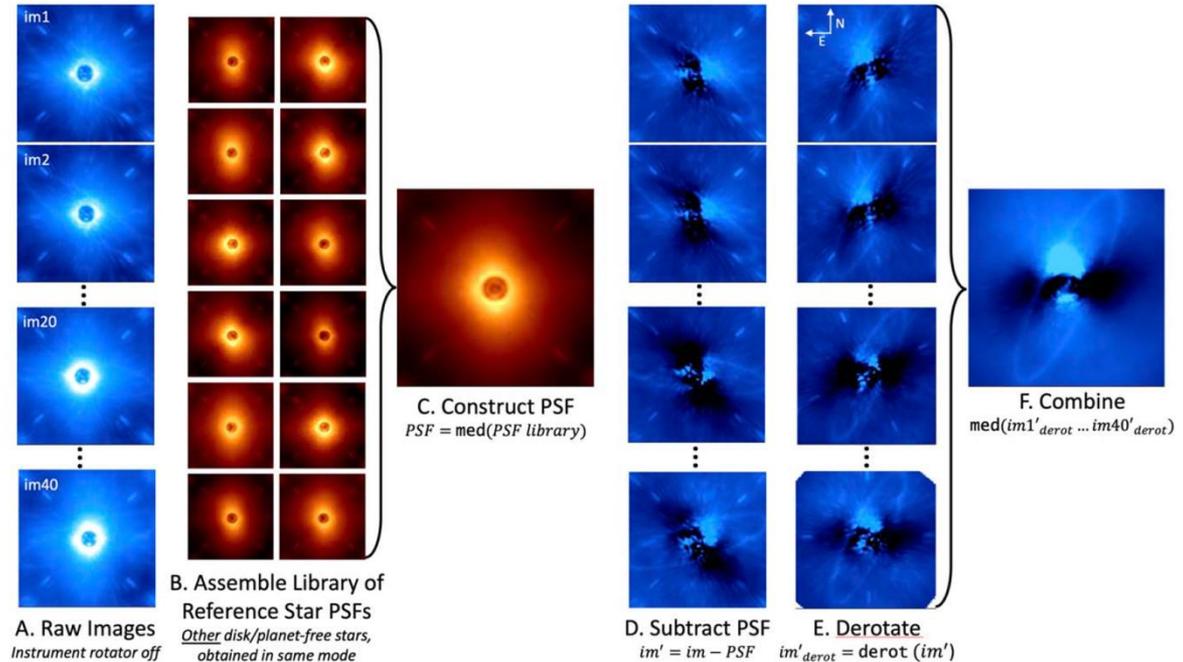

Reference Differential Imaging (RDI) → Requires reference star observations

Angular Differential Imaging (ADI) → Requires on-sky rotation

Reference Differential Imaging (RDI)

- RDI utilizes a library of images of stars other than the science target (Column B) obtained in the same observing mode.
- Generally, stars without any known disk or planet signal are chosen as reference
- PSF estimate is subtracted (Column D) to remove starlight in the image.

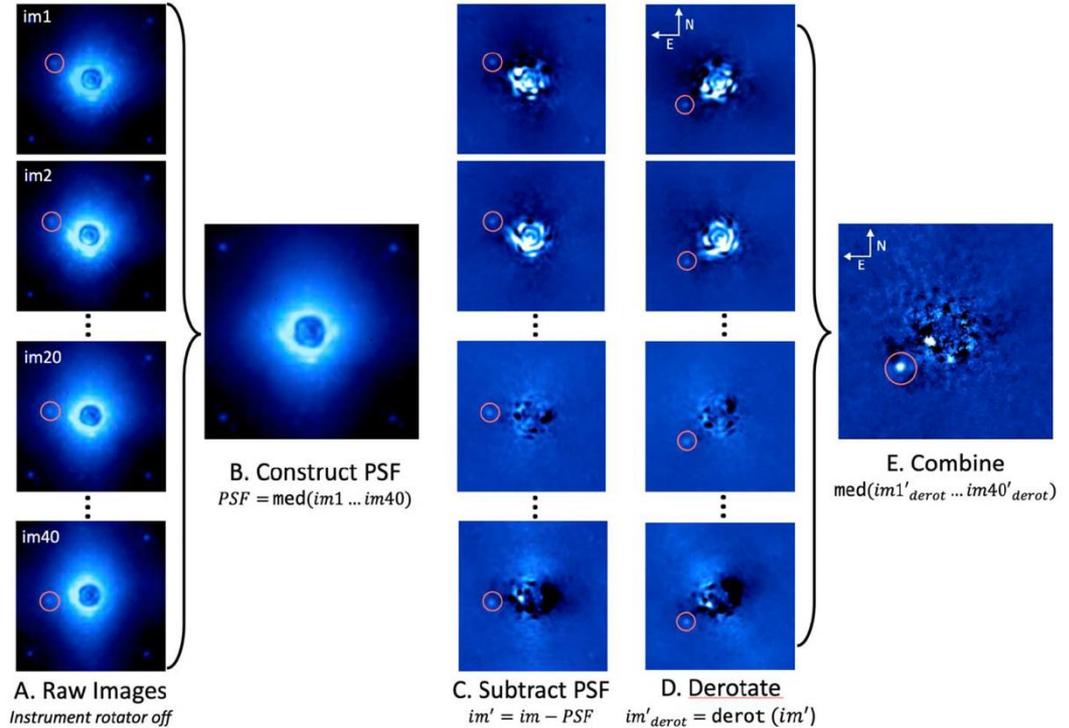

Credit: Follette 2023

Angular Differential Imaging (ADI)

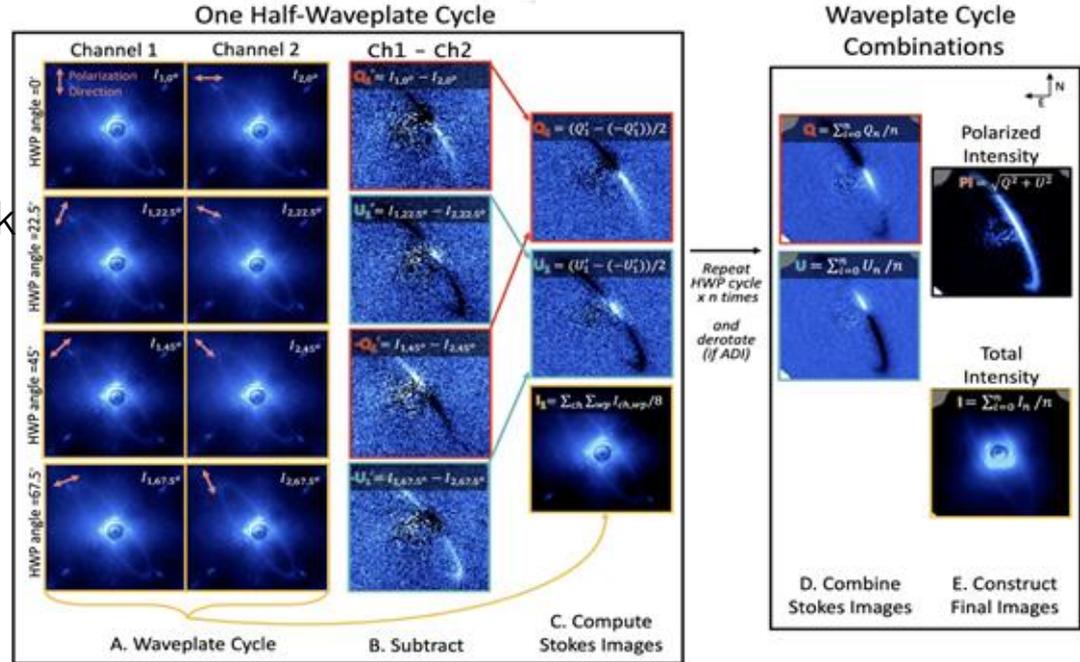

- Images are collected with the instrument rotator off.
- The instrumental PSF (including any quasi-static speckles) remains relatively stable in the instrument frame throughout the sequence, while real sources rotate with the sky

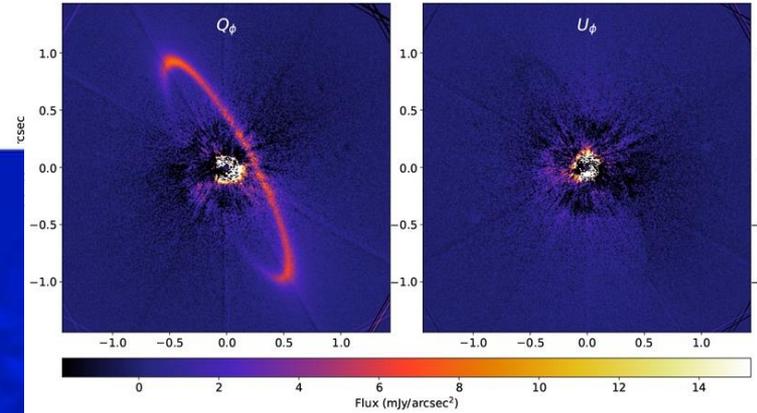

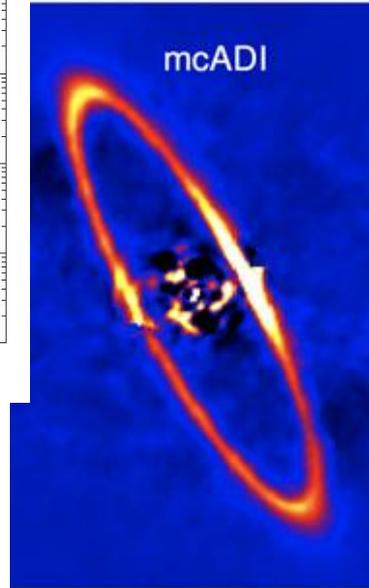

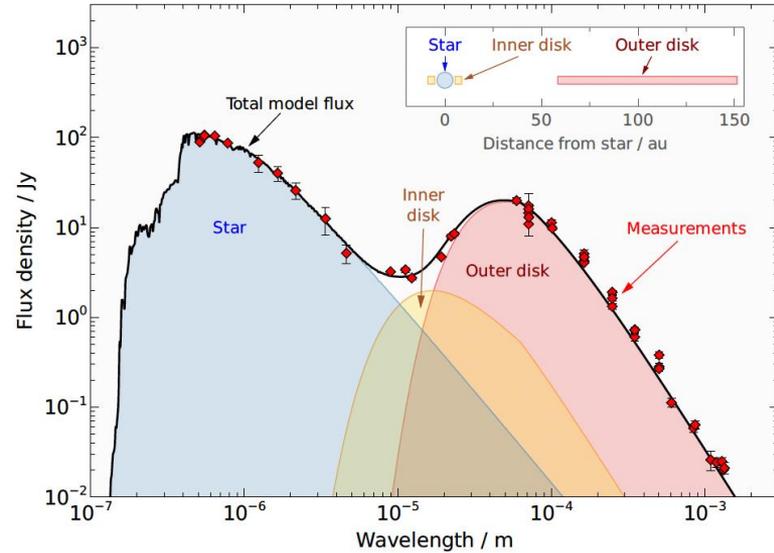

Polarized differential imaging

- The “Polarized Intensity” (PI) image (Column E) easily isolates the (polarized) light of the disk from the (unpolarized) starlight.
- The combined total intensity image, on the other hand (Column E, bottom), is dominated by starlight.

Credit: Follette 2023

SED, total intensity, polarization observations

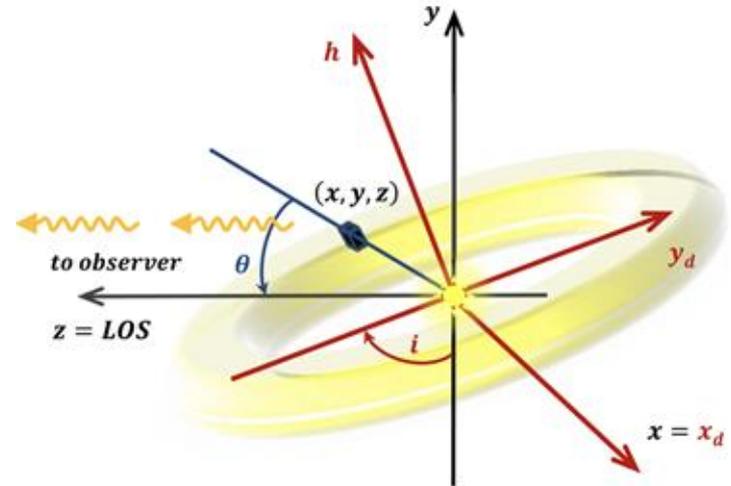

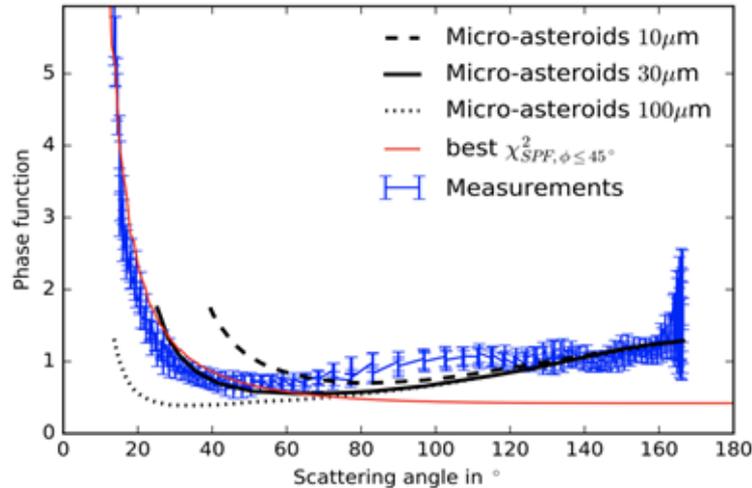

Scattering phase function (SPF)

Describes amount of light scattered by a dust grain at various scattering angles

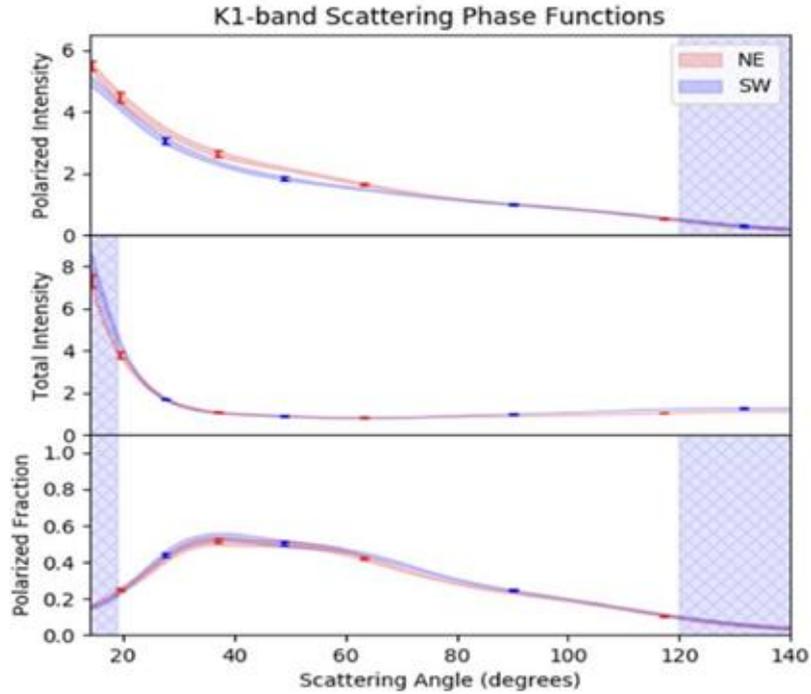

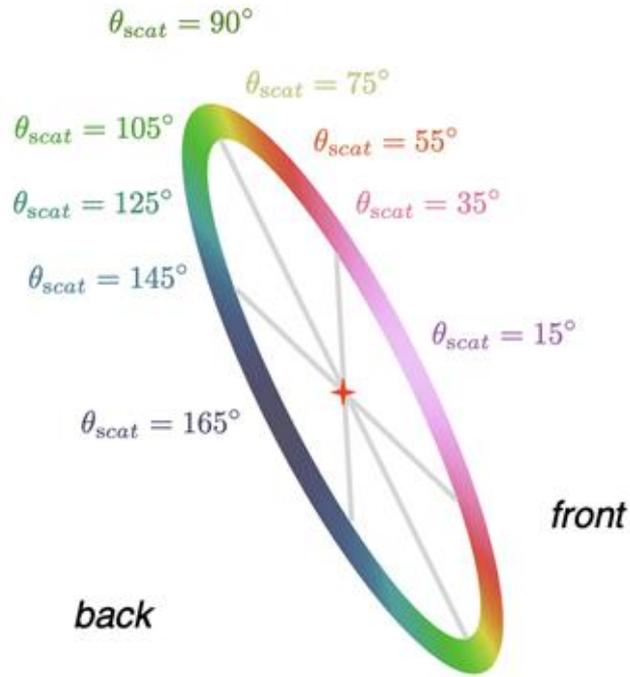

180° = back scattering

0° = forward scattering

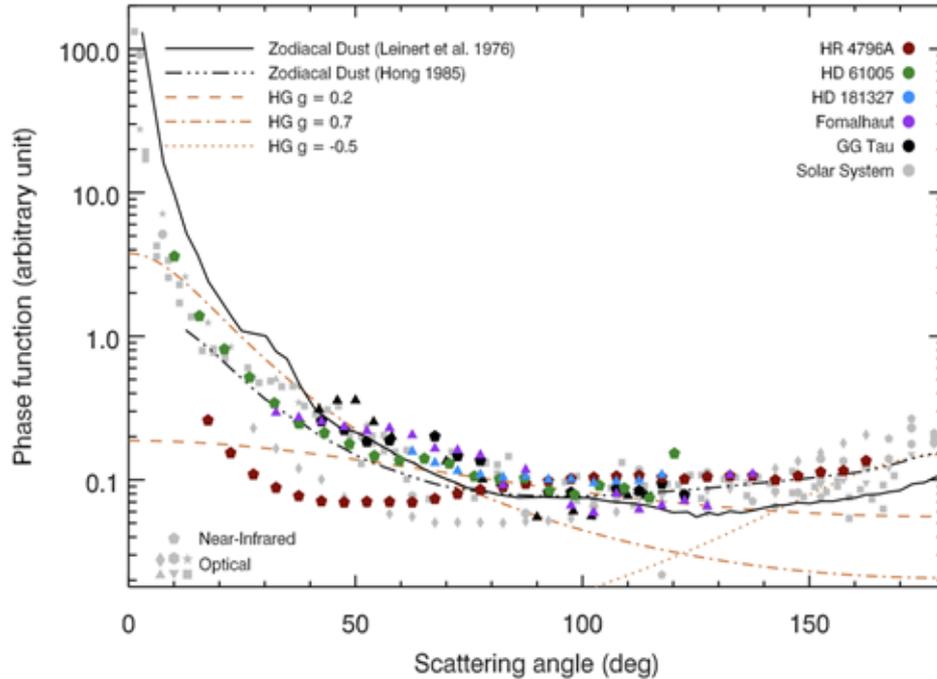

pSPF or polarization fraction

Heney-Greenstein Functions

The Heney-Greenstein phase function (1941):

$$p(\theta) = \frac{1}{4\pi} \frac{1 - g^2}{[1 + g^2 - 2g \cos(\theta)]^{3/2}}$$

Asymmetry Parameter:

$$g = \langle \cos(\theta) \rangle$$

$g > 0$: Forward Scattering

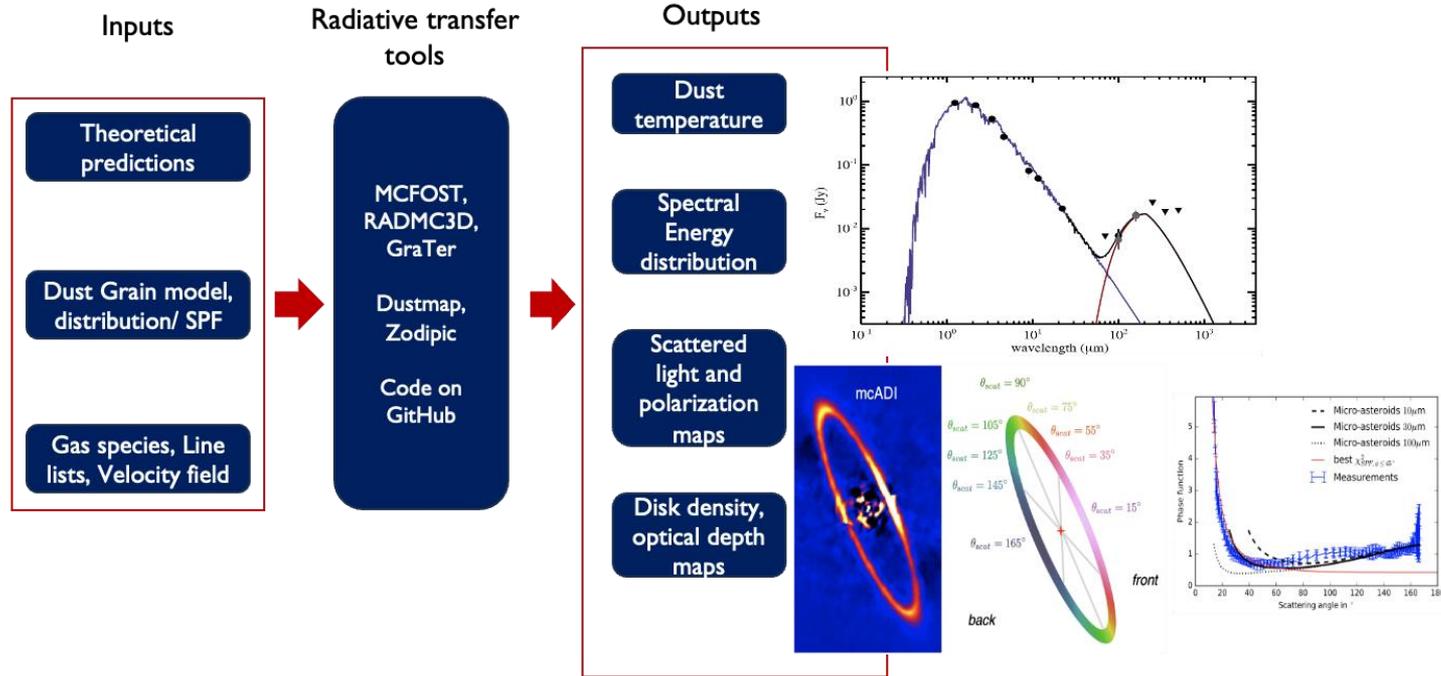

$g < 0$: Backward Scattering

$g = 0$: Isotropic Scattering

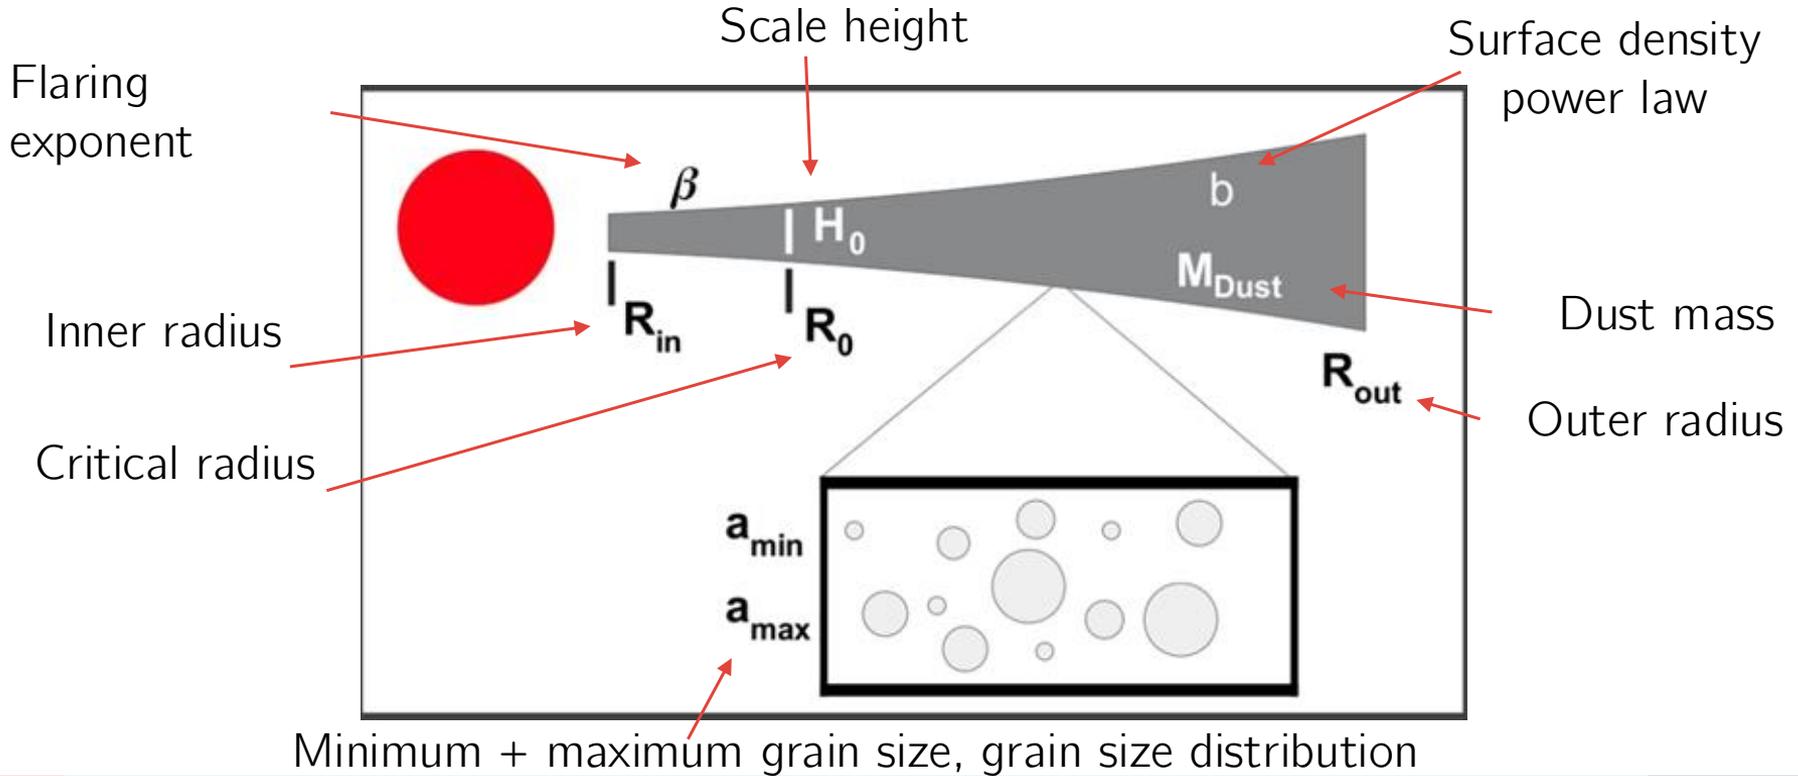

Radiative transfer modeling and disk properties

Radiative transfer describes how electromagnetic radiation is transmitted through a planetary atmosphere.

Modelling Debris disks in scattered light

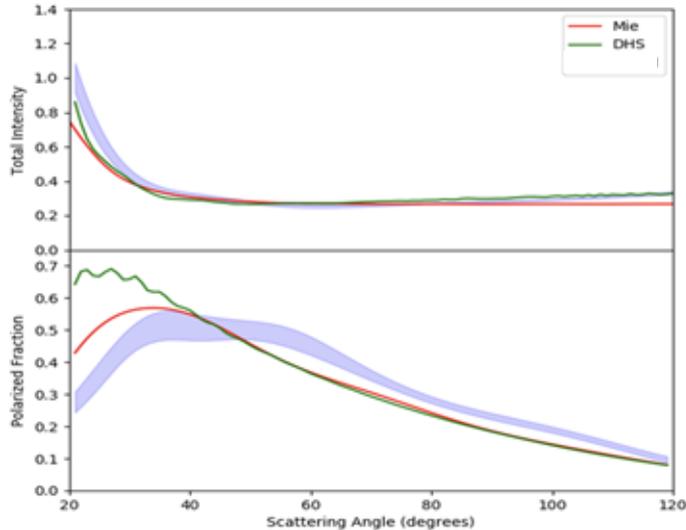

Dust scattering properties

- Size (+size distribution), shape, porosity and composition dictate the material and timescales for planet formation!
- Scattering efficiency depends on grain size
- We often use Mie scattering to model dust in debris disks as solid homogenous spheres, but it's not necessarily a great assumption!

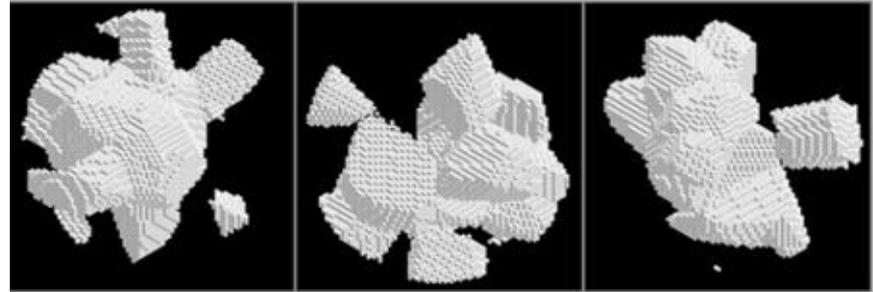

What limits our scattered light observations? Future directions

- Understanding of grain scattering theory: Observations are becoming incompatible with Mie theory/spherical grains. We need more sophisticated grain models to understand the scattering properties

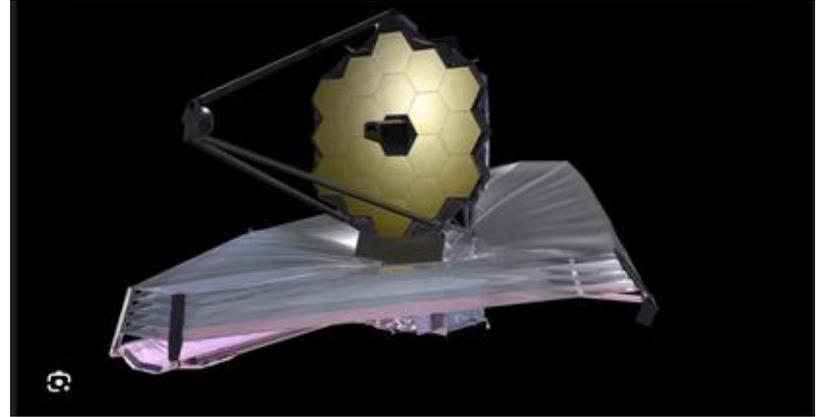

Irregular compact particles

What limits our scattered light observations? Future directions

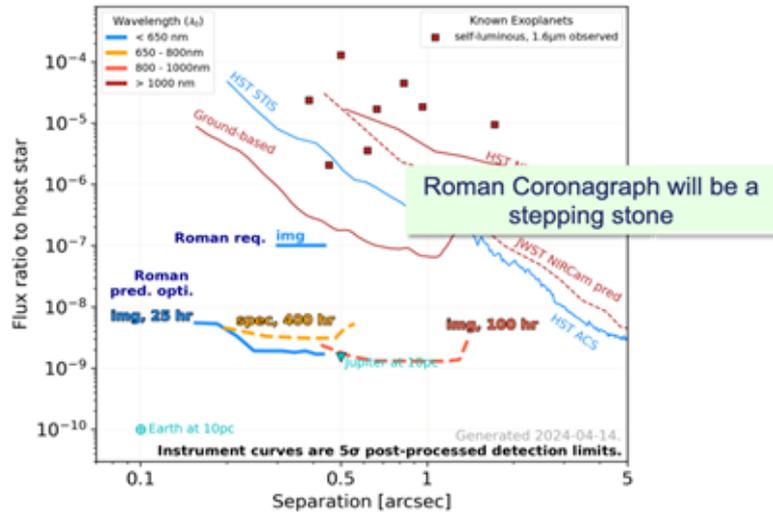

- Chemistry? – dust grain composition and optical constants
- **Laboratory measurements** of scattering dust grain Mueller matrices should inform, develop, and complement theories of dust grain scattering
- ALMA is helping to probe gas chemistry and JWST provide MIR spectroscopy probing water, silicates etc.

What limits our scattered light observations? Future directions

- Contrast limitations: **Better contrast with Roman and Polarimetry!!!!!!**

1 fully supported mode

Additional “best effort” modes: spectroscopy & polarimetry

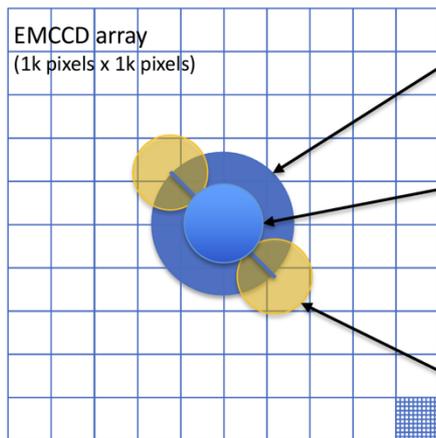

Band	λ_{center}	BW	Mode	FOV radius	FOV Coverage	Pol?	Coronagraph Mask Type	Support

Disk Hands-on session- Simulation of Disks through Roman CGI

- Disk models are in HLC and SPC folder
- Off-axis prfs are in prfs folder

 SPC

 prfs

 HLC

Disk Hands-on session- Simulation of Disks through Roman CGI

Pick a disk model – from HLC or SPC folders

If HLC – use the PRF for HLC – `prf_cube_HLC_B1.fits` and if SPC use `prf_cube_SPC_B4.fits`

2D scene inputs: disk model + PRF cube

For an extended scene (star + disk), we provide:

- a **disk model FITS** file (2D image of the disk brightness distribution), and
- a **PRF cube** (pre-computed PRF/PSF cube).

We collect these paths and scaling parameters in a dictionary (`twoD_scene_info`) that is passed into the extended-scene simulation.

```
# --- Disk path ---
main_path='/Users/polaris/Roman_winter_school/Corgisim_sims/fomalhaut/'
disk_model_path =main_path+'fomalhaut_disk_SPC_B4F.fits' # Path to the FITS file

# --- PRF path ---
prf_path = '/Users/polaris/Roman_winter_school/Corgisim_sims/corgisim_2D_convolution/prf_cube_SPC_B4F.fits' # Path to the PRF cube

# --- info needed for the extended scene simulation ---
twoD_scene_info = {
    'disk_model_path': disk_model_path,
    'prf_path': prf_path,
    'contrast': 10.0 # scaling factor for the disk model|
    # 'flux unit': str, # to be added by Chen
}
```

Disk Hands-on session- Simulation of Disks through Roman CGI

1. Follow the notebook – simulate the disk through the Coronagraph
2. Change the host star properties (look up Simbad) simulated image
3. For the same disk increase the contrast/scaling factor and see when the disk is not detectable

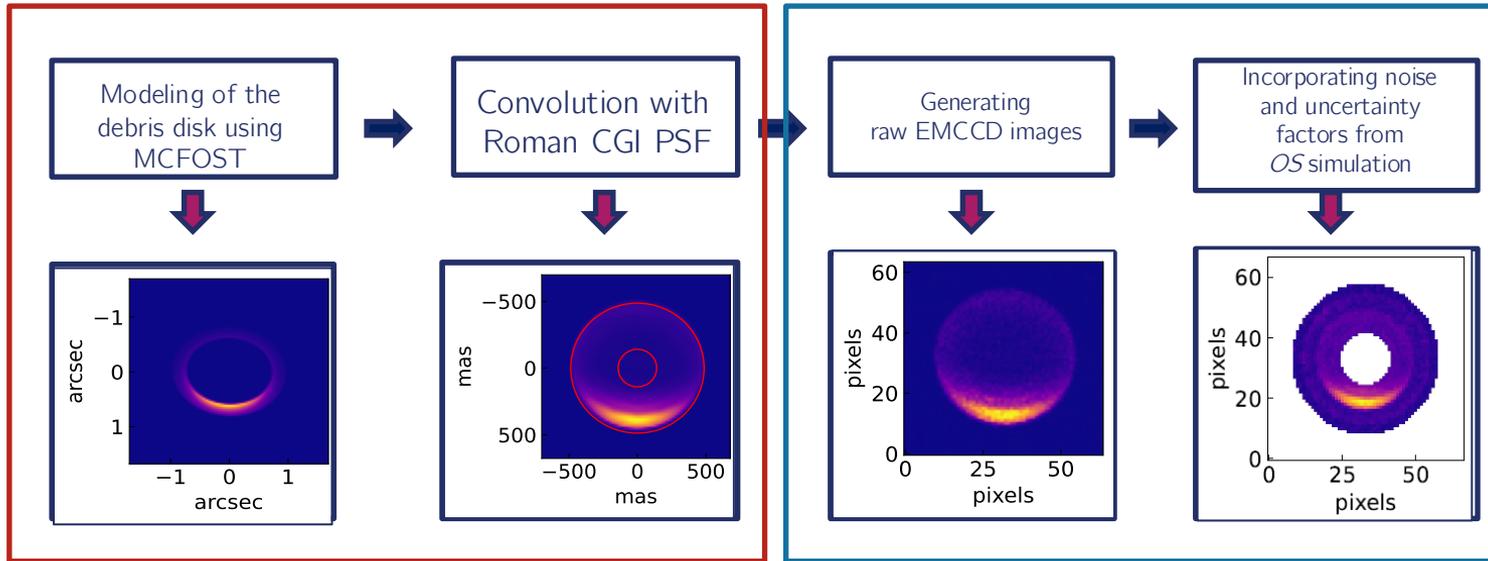

```
# --- Host star properties ---
Vmag = 1 # V-band magnitude
sptype = 'G0V' # Spectral type of
ref_flag = False # if the target is
host_star_properties = {'Vmag': Vmag,
                        'spectral_type': sptype,
                        'magtype': 'vegamag',
                        'ref_flag': False}
```

```
# --- info needed for the extended scene simulation ---?
twoD_scene_info = {
    'disk_model_path': disk_model_path,
    'prf_path': prf_path,
    'contrast': 10.0 # scaling factor for the disk model|
    # 'flux unit': str, # to be added by Chen
}
```

Disk Hands-on session- Time series observation sequence and perform RDI

- [spc_wfov_os11_frames_with_disk.fits](#): Temporal resampling [spc_wfov_os11_*darkhole*.fits](#) for 14.0 sec reference star images and 75.0 sec target star images; flux units remain e-/sec (no gain). 0.3 sec separation between frames allocated for readout time.
- [spc_wfov_os11_batch_info.txt](#): Text file listing parameters corresponding to entries, in sequence, in the file [spc_wfov_os11_frames_with_disk.fits](#) for each batch: batch ID, batch start time, star ID, roll, seconds per frame, gain, and number of frames.

Time series simulations notebook - illustrating how to process images through `emccd_detect` and `PhotonCount`. Takes as inputs the files listed above, adds EMCCD noise, converts to flux maps, and then does simple RDI to create post-processed planet/disk images. You can generate your own image stacks with different gain and exposure times, scenes, etc. Note that cosmic rays are NOT added.

Disk Hands-on session- Time series observation sequence and perform RDI

1. Look at the reference star, disk images at different rolls

 spc_wfov_os11_frames_with_disk.fits 

 me

 spc_wfov_os11_frames_with_disk_muf.fits 

 me

2. Run the notebook without MUFs and see the reduced disk images

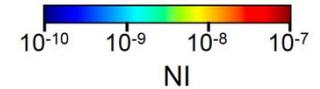

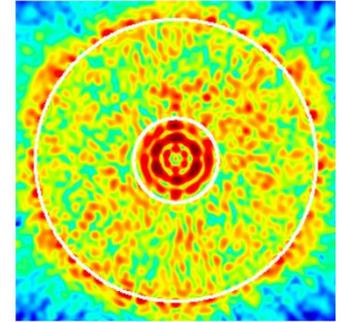

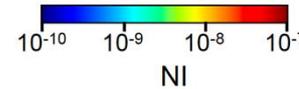

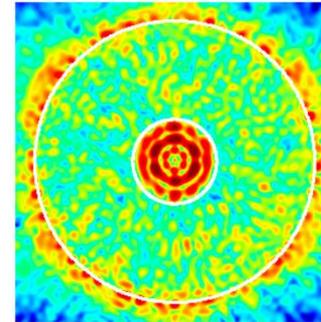

3. Run the notebook with MUFs and see the reduced images

Disk Hands-on session- Time series observation sequence and perform RDI

Current Modeling Uncertainty Factors (MUFs)

- STOP model (MUF always included)
 - 2x structural deformation MUF
 - increases beam shear, wavefront error drift by 2x
- Dynamic (vibration) model (MUFs always included)
 - Frequency-dependent jitter MUFs
 - 3x (<20 Hz), 4.27x (40-100 Hz), 8x (>100 Hz)
- Diffraction model (only when MUF is indicated)
 - Degraded dark hole contrast (uses the DM patterns from a few EFC iterations prior to the final solution)
 - Higher polarization-dependent aberrations
 - 1.5x higher aberrations
 - 2x higher contrast sensitivity to them
 - Higher pointing error sensitivity
 - 2x in contrast sensitivity (obtained by multiplying jitter by 1.6x)

Extra slides

Disk model parameters

The updated surface density profile $\eta(r, z)$ follows a smoothly connected two power-law structure described in more detail in Augereau et al. (1999) and given in Equation 1:

$$\eta(r, z) \propto R(r)Z(r, z) \quad (1)$$

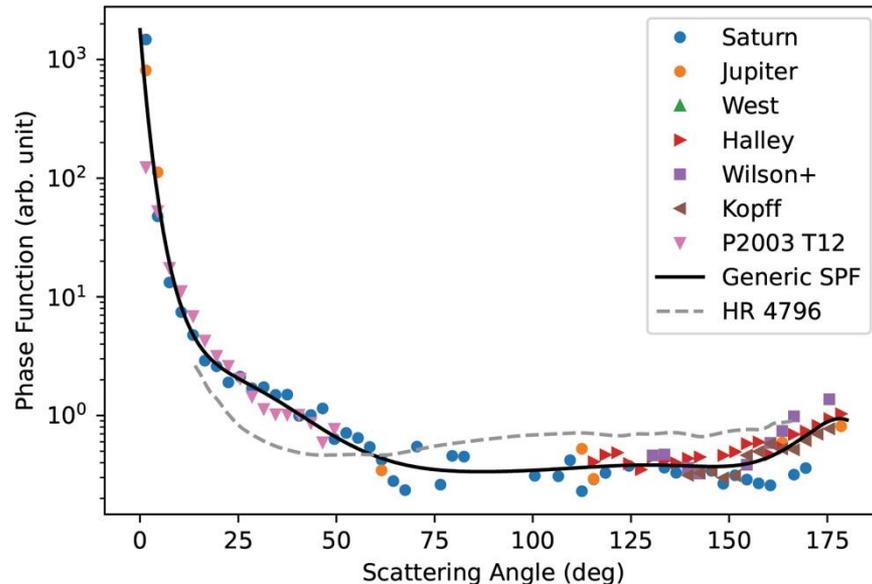

where $R(r)$ is given as:

$$R(r) \propto \left\{ \left(\frac{r}{R_c} \right)^{-2\alpha_{in}} + \left(\frac{r}{R_c} \right)^{-2\alpha_{out}} \right\}^{-\frac{1}{2}} \quad (2)$$

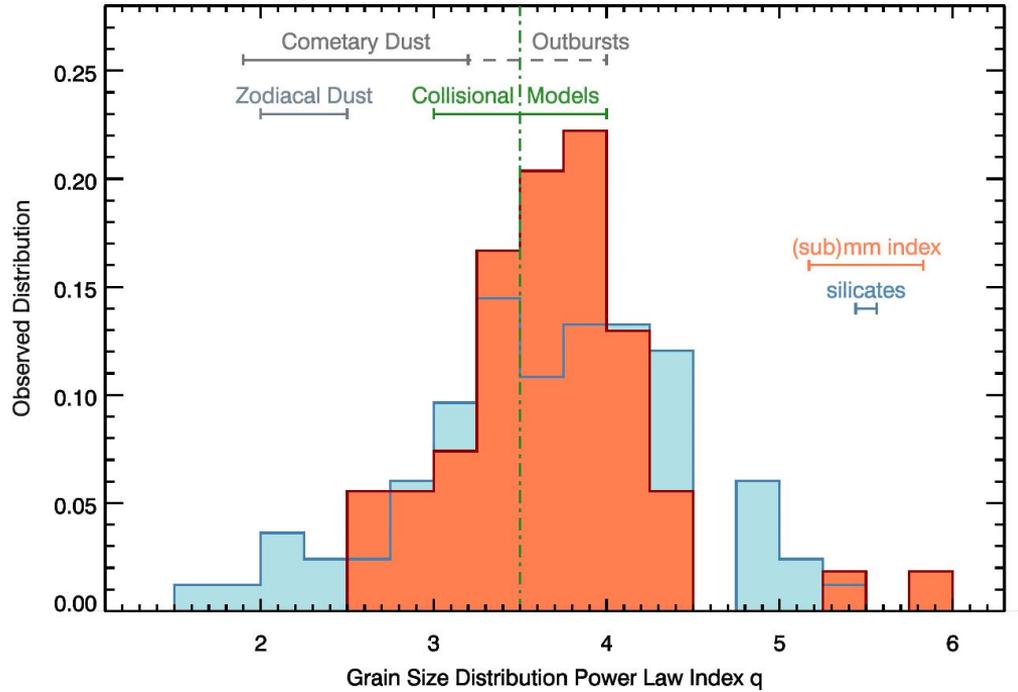

where r is the radial distance from the host star and R_c is the critical radius where a transition between two power law density regimes occurs. The indices of these power law density regimes are given as $\alpha_{in} > 0$ and $\alpha_{out} < 0$ for the inner and outer regions of the disk respectively. $Z(r, z)$ is given as

$$Z(r, z) \propto \exp\left(-\left(\frac{|z|}{h(r)}\right)^{\gamma_{vert}}\right) \quad (3)$$

where z is the distance from the disk midplane, γ_{vert} dictates the shape of the vertical density distribution, and $h(r)$ is the height above the disk midplane as a function of r . The Augereau et al. (1999) dust density profile was selected as it is more commonly used in dust density distribution analyses and therefore facilitates more consistent comparisons of our results to previous studies. For our analysis, we set $\gamma_{vert} = 2$ for a Gaussian vertical profile and $h(r)$ is given by $a_r \times r$ where a_r is the constant aspect ratio h/r , assuming a "bow-tie" shape for every disk. Both inner (R_{in}) and outer (R_{out}) cutoff radii define where the dust density $\eta(r, z)$ is treated as zero; only R_{in} is treated as a free parameter. All disks except for HD 110058 have evidence of extensive halo

Power law index
